Our motivating question:

# How should we organize and manage data?

- **Schemas:** *How should my data be logically organized?*
- **Normalization:** *Should my data have minimal dependency and redundancy?*
- **Views:** *What joins will be done most often?*
- **Access control:** *Should all users of the data have the same level of access*
- **DBMS:** *How do I pick between all the SQL and noSQL options?*
- and more!

It depends on the intended use of the data.

# Approaches to processing data

## OLTP

Online Transaction Processing

## OLAP

Online Analytical Processing

# Some concrete examples

## OLTP tasks

- Find the price of a book
- Update latest customer transaction
- Keep track of employee hours

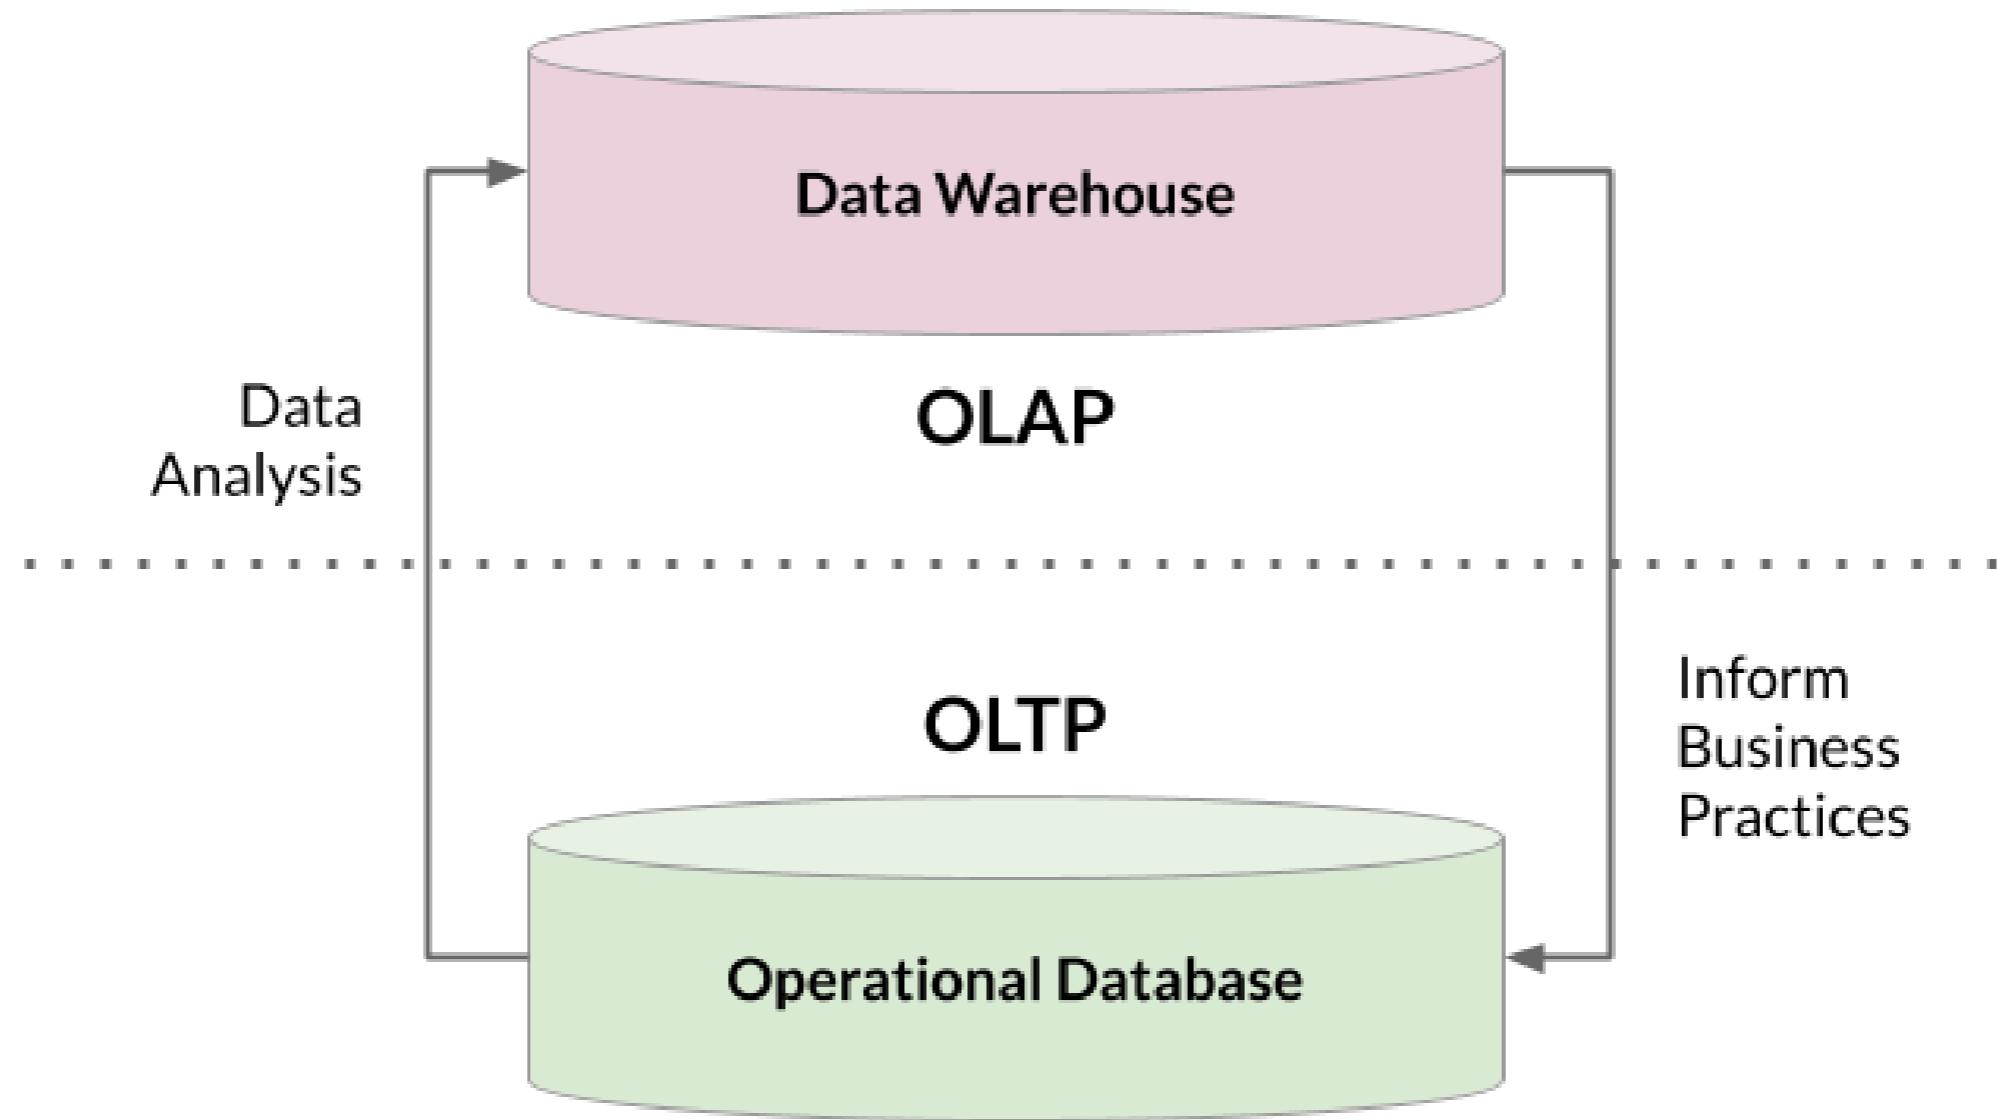

## OLAP tasks

- Calculate books with best profit margin
- Find most loyal customers
- Decide employee of the month

# OLAP vs. OLTP

|                | OLTP                                   | OLAP   |
|----------------|--|--|
| <i>Purpose</i> | support daily transactions             | report and analyze data                      |
| <i>Design</i>  | application-oriented                   | subject-oriented                             |
| <i>Data</i>    | up-to-date, operational                | consolidated, historical                     |
| <i>Size</i>    | snapshot, gigabytes                    | archive, terabytes                           |
| <i>Queries</i> | simple transactions & frequent updates | complex, aggregate queries & limited updates |
| <i>Users</i>   | thousands                              | hundreds                                     |

# Structuring data

## 1. Structured data

- Follows a schema
- Defined data types & relationships

*\_e.g., SQL, tables in a relational database \_*

## 3. Semi-structured data

- Does not follow larger schema
- Self-describing structure

*e.g., NoSQL, XML, JSON*

## 2. Unstructured data

- Schemaless
- Makes up most of data in the world

*e.g., photos, chat logs, MP3*

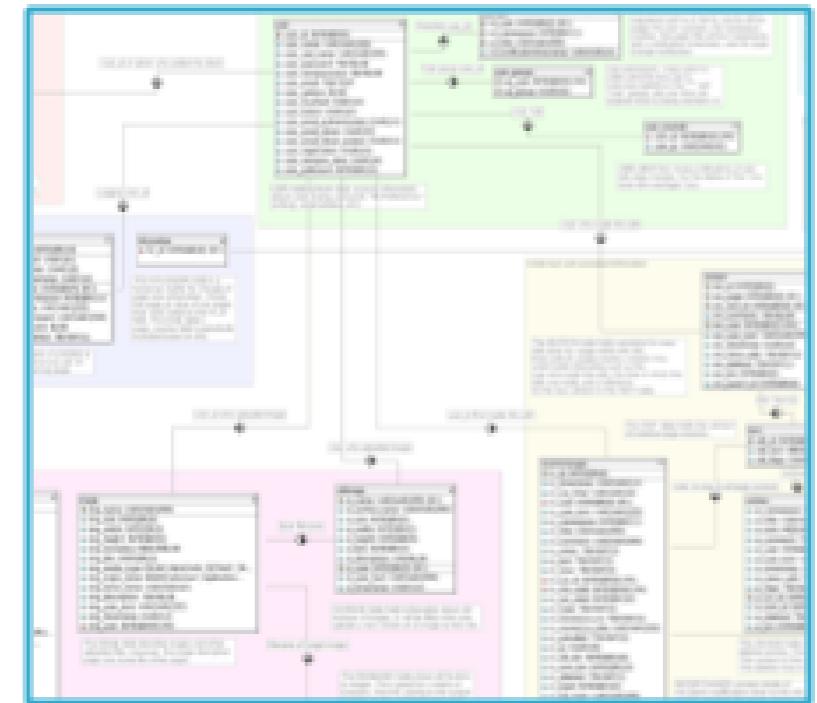

```
# Example of a JSON file
"user": {
    "profile_use_background_image": true,
    "statuses_count": 31,
    "profile_background_color": "CODEED",
    "followers_count": 3066,
    ...
}
```

# Storing data beyond traditional databases

- **Traditional databases**
  - For storing real-time relational structured data ? OLTP
- **Data warehouses**
  - For analyzing archived structured data ? OLAP
- **Data lakes**
  - For storing data of all structures = flexibility and scalability
  - For analyzing big data

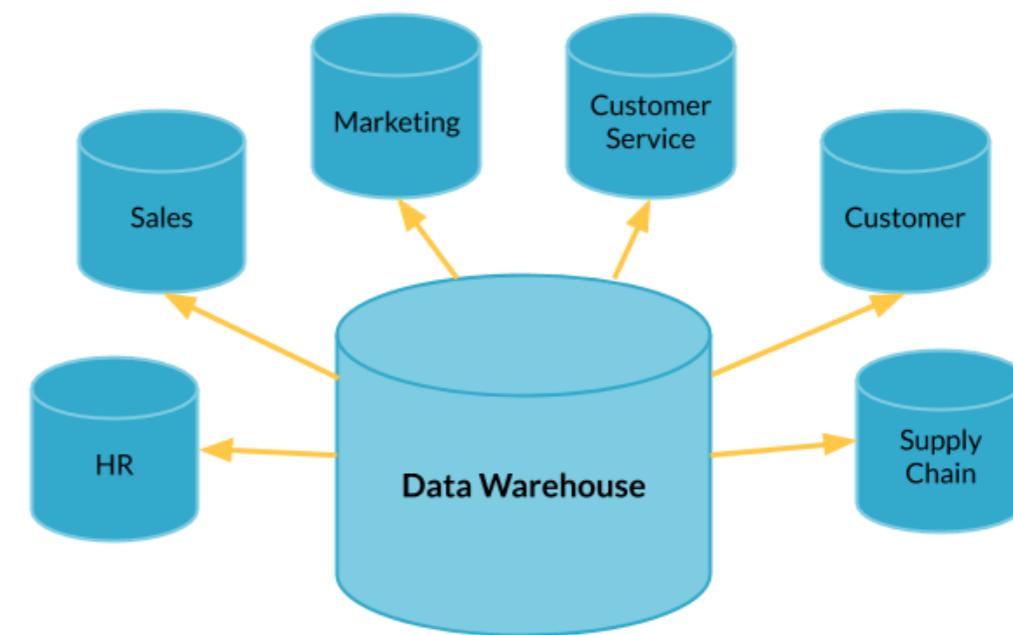

# Data warehouses

- Optimized for analytics - OLAP
  - Organized for reading/aggregating data
  - Usually read-only
- Contains data from multiple sources
- Massively Parallel Processing (MPP)
- Typically uses a denormalized schema and dimensional modeling

## Data marts

- Subset of data warehouses
- Dedicated to a specific topic

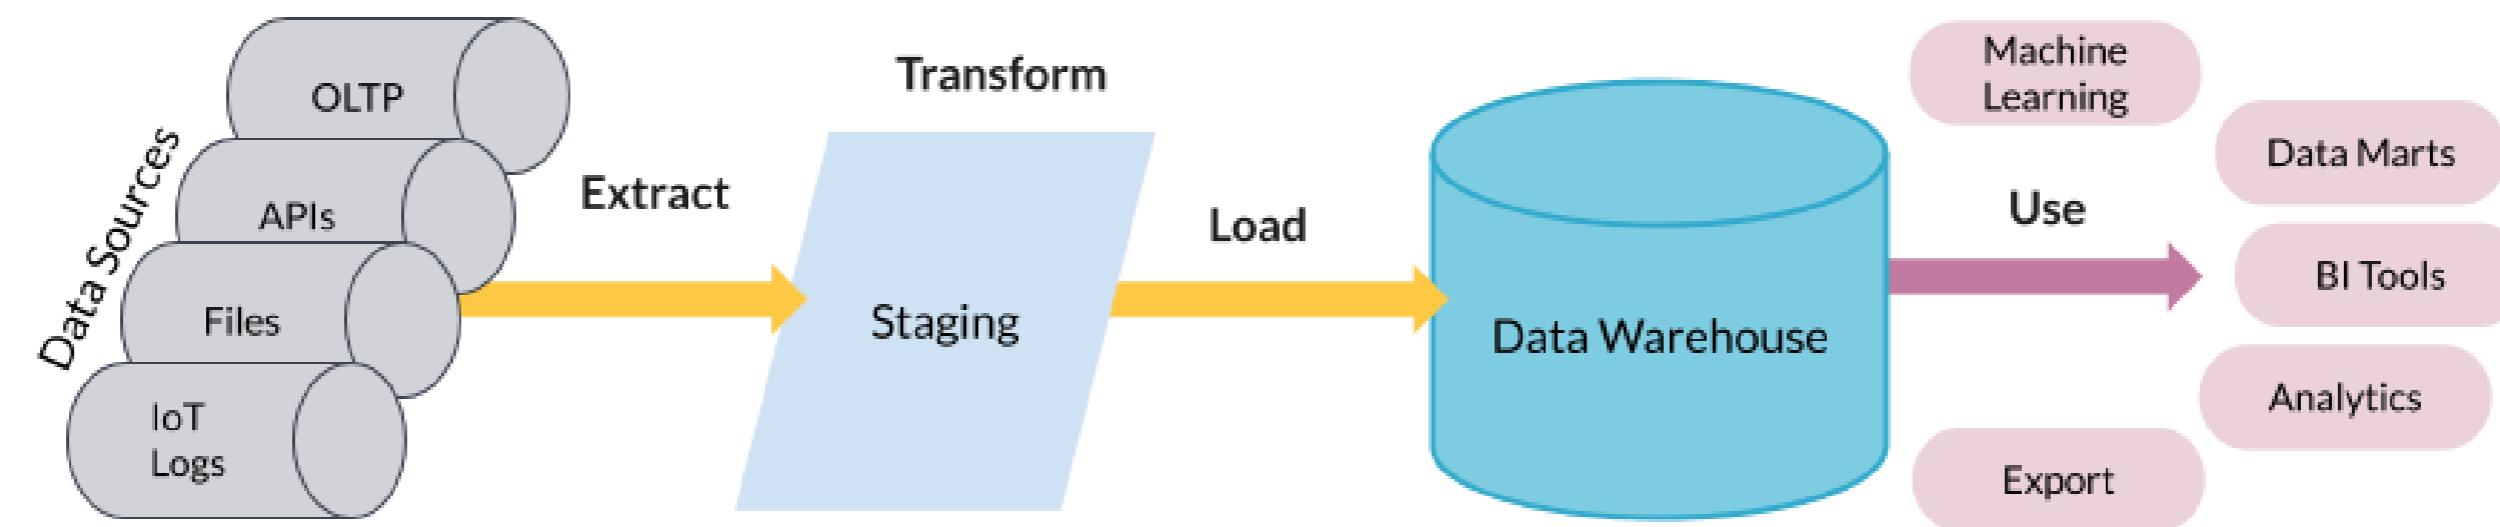

# Data lakes

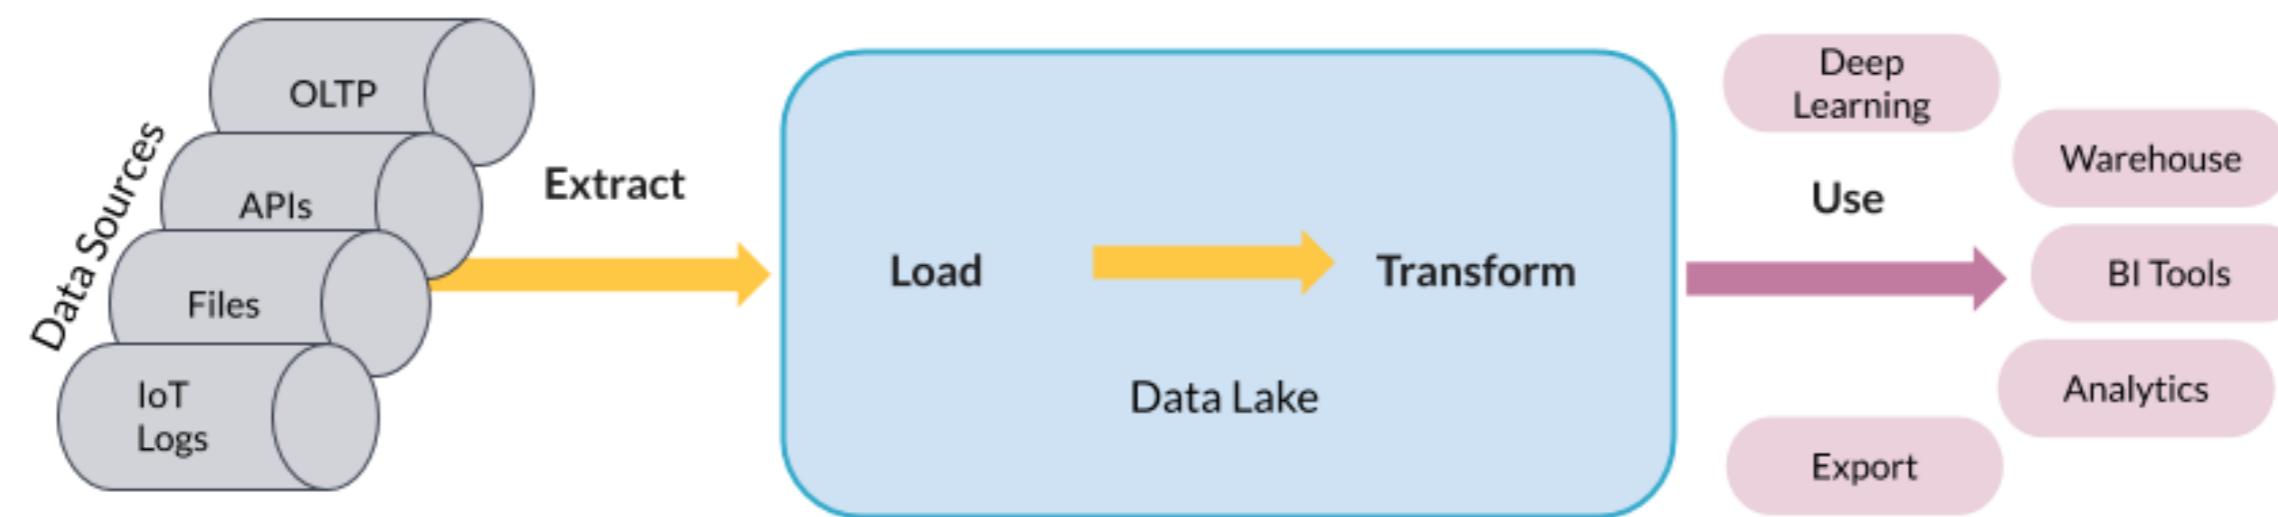

- Store *all* types of data at *a lower cost*:
  - e.g., raw, operational databases, IoT device logs, real-time, relational and non-relational
- Retains all data and can take up petabytes
- Schema-on-read as opposed to schema-on-write
- Need to catalog data otherwise becomes a **data swamp**
- Run **big data analytics** using services such as **Apache Spark** and **Hadoop**
  - Useful for deep learning and data discovery because activities require so much data

DATABASE DESIGN

# What is database design?

- Determines how data is logically stored
  - How is data going to be read and updated?
- Uses **database models**: high-level specifications for database structure
  - Most popular: relational model
  - Some other options: NoSQL models, object-oriented model, network model
- Uses **schemas**: blueprint of the database
  - Defines tables, fields, relationships, indexes, and views
  - When inserting data in relational databases, schemas must be respected

# Data modeling

Process of creating a *data model* for the data to be stored

**1. Conceptual data model:** describes entities, relationships, and attributes

- *Tools:* data structure diagrams, e.g., entity-relational diagrams and UML diagrams

**2. Logical data model:** defines tables, columns, relationships

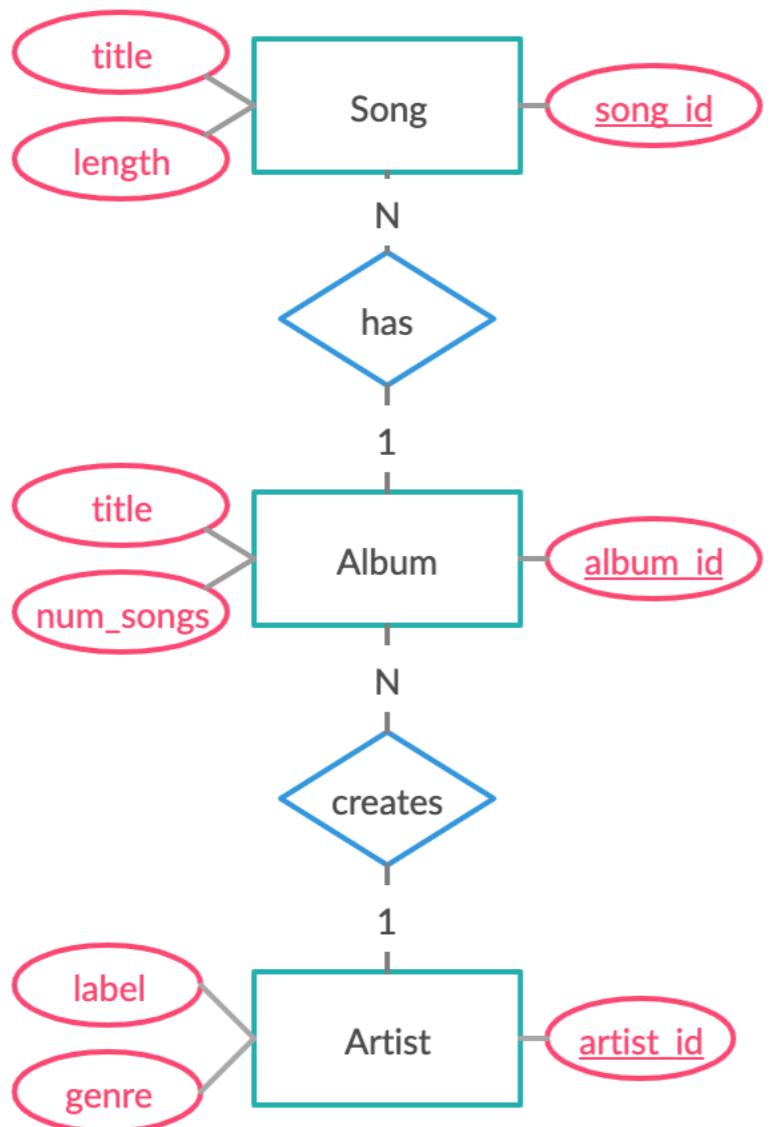

- *Tools:* database models and schemas, e.g., relational model and star schema

**3. Physical data model:** describes physical storage

- *Tools:* partitions, CPUs, indexes, backup systems and tablespaces

<sup>1</sup> [https://en.wikipedia.org/wiki/Data\\_model](https://en.wikipedia.org/wiki/Data_model)

# Conceptual - ER diagram

Entities, relationships, and attributes

# Logical - schema

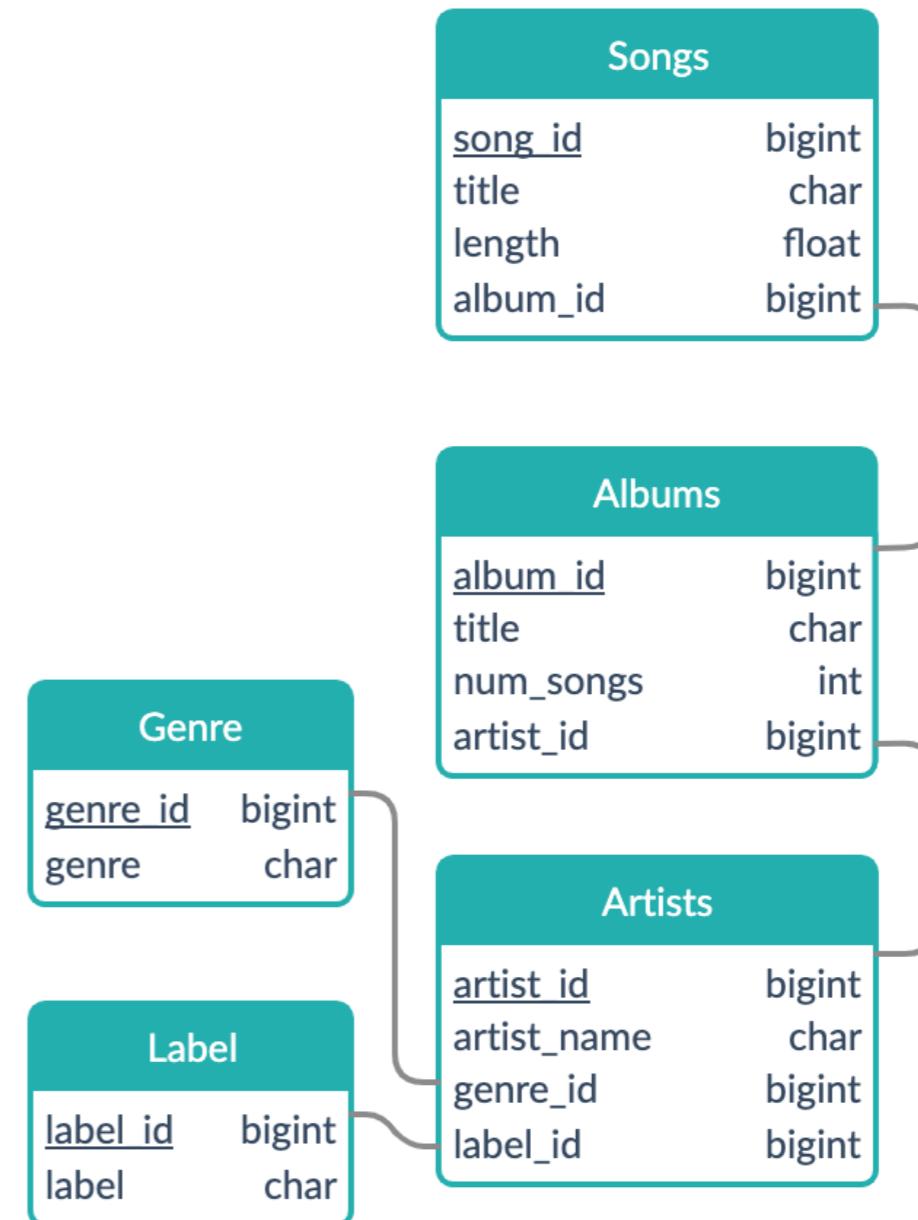

Fastest conversion: entities become the tables

# Other database design options

| Songs           |        |
|-----------------|--------|
| <u>song_id</u>  | bigint |
| song_title      | char   |
| length          | float  |
| album_title     | bigint |
| num_songs_album | int    |
| artist_name     | char   |
| genre           | char   |
| label           | char   |

## Determining tables

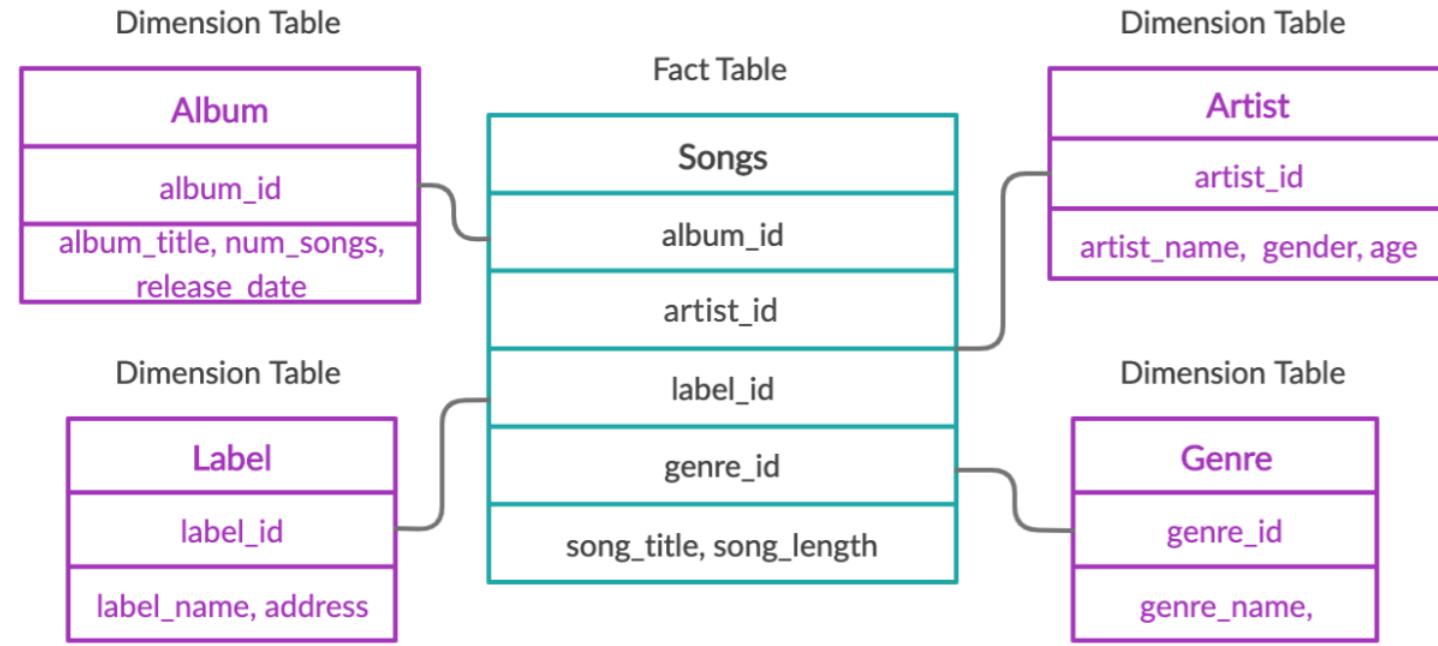

# Beyond the relational model

## Dimensional modeling

Adaptation of the relational model for data warehouse design

- Optimized for OLAP queries: aggregate data, not updating (OLTP)
- Built using the star schema
- Easy to interpret and extend schema

# Elements of dimensional modeling

## Organize by:

- What is being analyzed?
- How often do entities change?

## Fact tables

- Decided by business use-case
- Holds records of a metric
- Changes regularly
- Connects to dimensions via foreign keys

## Dimension tables

- Holds descriptions of attributes
- Does not change as often
